

# Plant Cycle

Plants or blossoms on the plants make seeds. Sometimes the seeds are found inside the fruit of the plant. The seed is the very first stage of the plant cycle. Pollen helps to make the seeds, wind or animals carry the pollen from one plant to another which then helps develop the seed. When the seed gets planted into soil, it will start to grow into a seedling, then the seedling will develop roots and eventually a stem and leaves. Then it will develop into a young plant. Look at the images below and explain the change and development at each stage.
